### ABSTRACT

In the  $n^+(p^+) - p(n)$   $\text{InSb}_{1-x}\text{As}_x$ - crystalline alloy, all the numerical results of electrical-and-thermoelectric coefficients, obtained in our previous work (Van Cong, 2018; Van Cong et al., 1984), are now revised and performed, by basing on our basic expressions, given Equations (1, 3, 5, 7, 11, 14, 19). Some remarkable results could be cited in the following. In Tables 5n (5p) given Appendix 1, for a given impurity density  $N$  and with increasing temperature  $T$ , and then in Tables 6n(6p) given Appendix 1, for a given  $T$  and with decreasing  $N$ , the reduced Fermi-energy  $\xi_{n(p)}$  decreases, and other thermoelectric coefficients are in variations, as indicated by the arrows as: (increase:  $\nearrow$ , decrease:  $\searrow$ ). Further, one notes in these Tables that with increasing  $T$  (or with decreasing  $N$ ) one obtains: (i) for  $\xi_{n(p)} \simeq 1.8138$ , while the numerical results of the Seebeck coefficient  $S$  present a same

minimum  $(S)_{\min} \left( \simeq -1.563 \times 10^{-4} \frac{V}{K} \right)$ , those of the figure of merit  $ZT$  show a same maximum  $(ZT)_{\max} = 1$ , (ii) for  $\xi_{n(p)} = 1$ ,  $S$ ,  $ZT$ , the Mott figure of merit  $(ZT)_{\text{Mott}}$ , the Van-Cong coefficient  $VC$ , and the Thomson coefficient  $Ts$  present the same results:  $-1.322 \times 10^{-4} \frac{V}{K}$ , 0.715, 3.290,  $-1.105 \times 10^{-4} \frac{V}{K}$ , and  $1.657 \times 10^{-4} \frac{V}{K}$ , respectively, and (iii) for  $\xi_n \simeq 1.8138$ ,  $(ZT)_{\text{Mott}} = 1$ . It seems that these same results could present a new law in the thermoelectric properties, obtained in the degenerate case.

**KEYWORDS:** Electrical conductivity, Seebeck coefficient, Figure of merit, Van-Cong coefficient, Thomson coefficient, Peltier coefficient.

## INTRODUCTION

In the  $n^+(p^+) - p(n)$   $\text{InSb}_{1-x}\text{As}_x$ - crystalline alloy, all the numerical results of electrical-and-thermoelectric coefficients, obtained in our previous work (Van Cong, 2018; Van Cong et al., 1984), are now revised and performed, by basing on our following basic expressions (Van Cong, 1980 and 2024; Van Cong and Debiais, 1993; Van Cong and Doan Khanh, 1992).

(1) The effective extrinsic static dielectric constant law,  $\epsilon(r_{d(a)}, x)$ , due to the impurity size effect, is determined in Eq. (1).

(2) The generalized Mott criterium in the metal-insulator transition is expressed in Equations (3, 5, 6), showing that  $N_{CDn(CDp)}$  is just **the density of electrons (holes) localized in the exponential conduction (valence)-band tail,  $N_{CDn(CDp)}^{EBT}$** , with a precision of the order of  $2.86 \times 10^{-7}$ , as given in our recent work (Van Cong, 2024), and the effective electron (hole)-density:  $N^* \equiv N - N_{CDn(CDp)} \simeq N - N_{CDn(CDp)}^{EBT}$ , as that observed in the compensated crystals.

(3) The ratio of the inverse effective screening length  $k_{sn(sp)}$  to Fermi wave number  $k_{Fn(kp)}$  at 0 K,  $R_{sn(sp)}(N^*)$ , defined in Eq. (7), is valid at any density  $N^*$ .

(4) The Fermi energy for any  $N$  and  $T$ ,  $E_{Fn(Fp)}$ , determined in Eq. (11) with a precision of the order of  $2.11 \times 10^{-4}$  (Van Cong, 1993), and it is present in all the expressions of electrical-and-thermoelectric coefficients.

(v) Our expressions for the electrical conductivity,  $\sigma$ , and for the Seebeck coefficient,  $S$ , determined respectively in Equations (14, 19) are the basic expressions for determining the following electrical-and-thermoelectric coefficients.

## OUR STATIC DIELECTRIC CONSTANT LAW-AND-GENERALIZED MOTT CRITERIUM IN THE METAL-INSULATOR TRANSITION

First of all, in the  $n^+(p^+) - p(n)$   $X(x) \equiv \text{InSb}_{1-x}\text{As}_x$ - crystalline alloy at  $T=0$  K, we denote the donor (acceptor) d(a)-radius by  $r_{d(a)}$ , the corresponding intrinsic one by:  $r_{do(ao)} = r_{Sb(\text{In})}$ ,

the unperturbed relative effective electron (hole) mass in conduction (valence) bands by:  $m_{c(v)}(x)/m_o$ , the unperturbed relative static dielectric constant by:  $\epsilon_o(x)$ . Then, their values are reported in **Table 1 in Appendix 1**.

Therefore, we can define the effective donor (acceptor)-ionization energy in absolute values as:

$$E_{do(ao)}(x) = \frac{136.00 \times [m_{c(v)}(x)/m_o]}{[\epsilon_o(x)]^2} \text{ meV}, \text{ and then, the isothermal bulk modulus, by:}$$

$$B_{do(ao)}(x) \equiv \frac{E_{do(ao)}(x)}{\left(\frac{4\pi}{3}\right) \times (r_{do(ao)})^3}.$$

### Effect of Impurity $r_{d(a)}$ -size, with a given $x$

Here, the changes in all the energy-band-structure parameters, expressed in terms of the effective relative dielectric constant  $\epsilon(r_{d(a)}, x)$ , developed as follows.

At  $r_{d(a)} = r_{do(ao)}$ , the needed boundary conditions are found to be, for the impurity-atom volume  $V = (4\pi/3) \times (r_{d(a)})^3$ ,  $V_{do(ao)} = (4\pi/3) \times (r_{do(ao)})^3$ , for the pressure  $p$ ,  $p_o = 0$ , and for the deformation potential energy (or the strain energy)  $\sigma$ ,  $\sigma_o = 0$ . Further, the two important equations (Van Cong, 1984 and 2018), used to determine the  $\sigma$ -variation,  $\Delta\sigma \equiv \sigma - \sigma_o = \sigma$ , are defined by:  $\frac{dp}{dV} = -\frac{B}{V}$  and  $p = \frac{d\sigma}{dV}$ . giving:  $\frac{d}{dV} \left( \frac{d\sigma}{dV} \right) = \frac{B}{V}$ . Then, by an integration, one gets:

$$\left[ \Delta\sigma(r_{d(a)}, x) \right]_{n(p)} = B_{do(ao)}(x) \times (V - V_{do(ao)}) \times \ln \left( \frac{V}{V_{do(ao)}} \right) = E_{do(ao)}(x) \times \left[ \left( \frac{r_{d(a)}}{r_{do(ao)}} \right)^3 - 1 \right] \times \ln \left( \frac{r_{d(a)}}{r_{do(ao)}} \right)^3 \geq 0.$$

Furthermore, we also shown that, as  $r_{d(a)} > r_{do(ao)}$  ( $r_{d(a)} < r_{do(ao)}$ ), the compression (dilatation) gives rise to the increase (the decrease) in the energy gap  $E_{gap(gp)}(r_{d(a)}, x)$ , and the effective donor (acceptor)-ionization energy  $E_{d(a)}(r_{d(a)}, x)$  in absolute values, obtained in the effective Bohr model, which is represented respectively by:  $\pm \left[ \Delta\sigma(r_{d(a)}, x) \right]_{n(p)}$ ,

$$E_{gap(gp)}(r_{d(a)}, x) - E_{go}(x) = E_{d(a)}(r_{d(a)}, x) - E_{do(ao)}(x) = E_{do(ao)}(x) \times \left[ \left( \frac{\epsilon_o(x)}{\epsilon(r_{d(a)})} \right)^2 - 1 \right] = + \left[ \Delta\sigma(r_{d(a)}, x) \right]_{n(p)},$$

for  $r_{d(a)} \geq r_{do(ao)}$ , and for  $r_{d(a)} \leq r_{do(ao)}$ ,

$$E_{gn(gpo)}(r_{d(a)}, x) - E_{go}(x) = E_{d(a)}(r_{d(a)}, x) - E_{do(ao)}(x) = E_{do(ao)}(x) \times \left[ \left( \frac{\varepsilon_0(x)}{\varepsilon(r_{d(a)})} \right)^2 - 1 \right] = - [\Delta\sigma(r_{d(a)}, x)]_{n(p)}$$

Therefore, one obtains the expressions for relative dielectric constant  $\varepsilon(r_{d(a)}, x)$  and energy band gap  $E_{gn(gp)}(r_{d(a)}, x)$ , as:

(i)-for  $r_{d(a)} \geq r_{do(ao)}$ , since  $\varepsilon(r_{d(a)}, x) = \frac{\varepsilon_0(x)}{\sqrt{1 + \left[ \left( \frac{r_{d(a)}}{r_{do(ao)}} \right)^3 - 1 \right] \times \ln \left( \frac{r_{d(a)}}{r_{do(ao)}} \right)^3}} \leq \varepsilon_0(x)$ , being a new  $\varepsilon(r_{d(a)}, x)$ -law,

$$E_{gn(gpo)}(r_{d(a)}, x) - E_{go}(x) = E_{d(a)}(r_{d(a)}, x) - E_{do(ao)}(x) = E_{do(ao)}(x) \times \left[ \left( \frac{r_{d(a)}}{r_{do(ao)}} \right)^3 - 1 \right] \times \ln \left( \frac{r_{d(a)}}{r_{do(ao)}} \right)^3 \geq 0, \quad (1a)$$

according to the increase in both  $E_{gn(gp)}(r_{d(a)}, x)$  and  $E_{d(a)}(r_{d(a)}, x)$ , with increasing  $r_{d(a)}$  and for a given x, and

(ii)-for  $r_{d(a)} \leq r_{do(ao)}$ , since  $\varepsilon(r_{d(a)}, x) = \frac{\varepsilon_0(x)}{\sqrt{1 - \left[ \left( \frac{r_{d(a)}}{r_{do(ao)}} \right)^3 - 1 \right] \times \ln \left( \frac{r_{d(a)}}{r_{do(ao)}} \right)^3}} \geq \varepsilon_0(x)$ , with a condition, given by:  $\left[ \left( \frac{r_{d(a)}}{r_{do(ao)}} \right)^3 - 1 \right] \times \ln \left( \frac{r_{d(a)}}{r_{do(ao)}} \right)^3 < 1$ , being a new  $\varepsilon(r_{d(a)}, x)$ -law,

$$E_{gn(gpo)}(r_{d(a)}, x) - E_{go}(x) = E_{d(a)}(r_{d(a)}, x) - E_{do(ao)}(x) = -E_{do(ao)}(x) \times \left[ \left( \frac{r_{d(a)}}{r_{do(ao)}} \right)^3 - 1 \right] \times \ln \left( \frac{r_{d(a)}}{r_{do(ao)}} \right)^3 \leq 0, \quad (1b)$$

corresponding to the decrease in both  $E_{gn(gp)}(r_{d(a)}, x)$  and  $E_{d(a)}(r_{d(a)}, x)$ , with decreasing  $r_{d(a)}$  and for a given x; therefore, the effective Bohr radius  $a_{Bn(Bp)}(r_{d(a)}, x)$  is defined by:

$$a_{Bn(Bp)}(r_{d(a)}, x) \equiv \frac{\varepsilon(r_{d(a)}, x) \times \hbar^2}{m_{c(v)}(x) \times m_0 \times q^2} = 0.53 \times 10^{-8} \text{ cm} \times \frac{\varepsilon(r_{d(a)}, x)}{m_{c(v)}(x)}. \quad (2)$$

### Generalized Mott Criterium in the Metal-Insulator Transition

Furthermore, it is interesting to remark that the critical total donor (acceptor)-density in the metal-insulator transition (MIT) at T=0 K,  $N_{CDn(NDp)}(r_{d(a)}, x)$ , was given by the Mott's criterium, with an empirical parameter,  $M_{n(p)}$ , as:

$$N_{CDn(CDp)}(r_{d(a)}, x)^{1/3} \times a_{Bn(Bp)}(r_{d(a)}, x) = M_{n(p)}, M_{n(p)} = 0.25, \quad (3)$$

depending thus on our new  $\varepsilon(r_{d(a)}, x)$ -law.

This excellent one can be explained from the definition of the reduced effective Wigner-Seitz (WS) radius  $r_{sn(sp)}$ , characteristic of interactions, by:

$$r_{sn(sp)}(N, r_{d(a)}, x) \equiv \left(\frac{3}{4\pi N}\right)^{1/3} \times \frac{1}{a_{Bn(Bp)}(r_{d(a)}, x)} = 1.1723 \times 10^8 \times \left(\frac{1}{N}\right)^{1/3} \times \frac{m_{c(v)}(x) \times m_o}{\varepsilon(r_{d(a)}, x)}, \quad (4)$$

being equal to, in particular, at  $N=N_{CDn(CDp)}(r_{d(a)}, x)$ :  $r_{sn(sp)}(N_{CDn(CDp)}(r_{d(a)}, x), r_{d(a)}, x) = 2.4813963$ , for any  $(r_{d(a)}, x)$ -values. Then, from Eq. (4), one also has :

$$N_{CDn(CDp)}(r_{d(a)}, x)^{1/3} \times a_{Bn(Bp)}(r_{d(a)}, x) = \left(\frac{3}{4\pi}\right)^{\frac{1}{3}} \times \frac{1}{2.4813963} = 0.25 = (WS)_{n(p)} = M_{n(p)}, \quad (5)$$

**explaining thus the existance of the Mott's criterium**

Furthermore, by using  $M_{n(p)} = 0.25$ , according to the empirical Heisenberg parameter  $H_{n(p)} = 0.47137$ , as those given in our previous work (Van Cong, 2024), we have also showed that  $N_{CDn(CDp)}$  is just **the density of electrons (holes) localized in the exponential conduction (valence)-band tail**,  $N_{CDn(CDp)}^{EBT}$ , with a precision of the order of  $2.86 \times 10^{-7}$ .

It shoud be noted that the values of  $M_{n(p)}$  and  $H_{n(p)}$  could be chosen so that those of  $N_{CDn(CDp)}$  and  $N_{CDn(CDp)}^{EBT}$  are in good agreement with their experimental results.

Therefore, the density of electrons (holes) given in parabolic conduction (valence) bands can be defined, as that given in compensated materials, by:

$$N^*(N, r_{d(a)}, x) \equiv N - N_{CDn(NDp)}(r_{d(a)}, x) = N^*, \text{ for a presentation simplicity.} \quad (6)$$

In summary, as observed in Table 1 of our previous paper (Van Cong, 2024), one remarks that, for a given  $x$  and an increasing  $r_{d(a)}$ ,  $\varepsilon(r_{d(a)}, x)$  decreases, while  $E_{gno(epo)}(r_{d(a)}, x)$ ,  $N_{CDn(NDp)}(r_{d(a)}, x)$  and  $N_{CDn(CDp)}^{EBT}(r_{d(a)}, x)$  increase, affecting strongly all the physical properties, as those observed in following Sections.

## PHYSICAL MODEL

In the  $n^+(p^+) - p(n)$   $X(x) \equiv InSb_{1-x}As_x$ - crystalline alloy, if denoting the Fermi wave number by:  $k_{Fn(Fp)}(N^*) \equiv \left(\frac{3\pi^2 N^*}{\varepsilon_c(v)}\right)^{\frac{1}{3}}$ , the reduced effective Wigner-Seitz (WS) radius  $r_{sn(sp)}$ ,

characteristic of interactions, being given in Eq. (4), in which  $N$  is replaced by  $N^*$ , is now defined by:

$$\gamma \times r_{sn(sp)}(N^*) \equiv \frac{k_{Fn(Fp)}^{-1}}{a_{Bn(Bp)}} < 1,$$

being proportional to  $N^{*-1/3}$ . Here,  $\gamma = (4/9\pi)^{1/3}$ ,  $k_{Fn(Fp)}^{-1}$  means the averaged distance between ionized donors (acceptors), and  $a_{Bn(Bp)}(r_{d(a)}, x)$  is determined in Eq. (2).

Then, the ratio of the inverse effective screening length  $k_{sn(sp)}$  to Fermi wave number  $k_{Fn(kp)}$  at 0 K is defined by:

$$R_{sn(sp)}(N^*) \equiv \frac{k_{sn(sp)}}{k_{Fn(Fp)}} = \frac{k_{Fn(Fp)}^{-1}}{k_{sn(sp)}^{-1}} = R_{snWS(spWS)} + [R_{snTF(spTF)} - R_{snWS(spWS)}]e^{-r_{sn(sp)}} < 1, \quad (7)$$

**being valid at any  $N^*$**

Here, these ratios,  $R_{snTF(spTF)}$  and  $R_{snWS(spWS)}$ , can be determined as follows.

First, for  $N \gg N_{CDn(NDp)}(r_{d(a)}, x)$ , according to the **Thomas-Fermi (TF)-approximation**, the ratio  $R_{snTF(spTF)}(N^*)$  is reduced to

$$R_{snTF(spTF)}(N^*) \equiv \frac{k_{snTF(spTF)}}{k_{Fn(Fp)}} = \frac{k_{Fn(Fp)}^{-1}}{k_{snTF(spTF)}^{-1}} = \sqrt{\frac{4\gamma r_{sn(sp)}}{\pi}} \ll 1, \quad (8)$$

being proportional to  $N^{*-1/6}$ .

Secondly, for  $N \ll N_{CDn(NDp)}(r_{d(a)})$ , according to the **Wigner-Seitz (WS)-approximation**, the ratio  $R_{snWS(snWS)}$  is respectively reduced to

$$R_{sn(sp)WS}(N^*) \equiv \frac{k_{sn(sp)WS}}{k_{Fn}} = 0.5 \times \left( \frac{s}{\pi} - \gamma \frac{d[r_{sn(sp)}^2 \times E_{CE}(N^*)]}{dr_{sn(sp)}} \right), \quad (9)$$

where  $E_{CE}(N^*)$  is the majority-carrier correlation energy (CE), being determined by (Van Cong, 2018):

$$E_{CE}(N^*) = \frac{-0.87553}{0.0908 + r_{sn(sp)}} + \frac{\frac{0.87553}{0.0908 + r_{sn(sp)}} + \left(\frac{2[1-\ln(2)]}{\pi^2}\right) \times \ln(r_{sn(sp)}) - 0.093288}{1 + 0.03847728 \times r_{sn(sp)}^{1.67878876}}.$$

Furthermore, in the highly degenerate case, the physical conditions are found to be given by (Van Cong, 2018)

$$\frac{k_{Fn(Fp)}^{-1}}{a_{Bn(Bp)}} < \frac{\eta_{n(p)}}{E_{Fn0(Fpo)}} \equiv \frac{1}{A_{n(p)}} < \frac{k_{Fn(Fp)}^{-1}}{k_{sn(sp)}^{-1}} \equiv R_{sn(sp)} < 1, \quad \eta_{n(p)}(N^*) \equiv \frac{\sqrt{2\pi N^*}}{\varepsilon(r_{d(a)})} \times q^2 k_{sn(sp)}^{-1/2}, \quad (10)$$

which gives:  $A_{n(p)}(N^*) = \frac{E_{Fn(Fp)}(N^*)}{\eta_{n(p)}(N^*)}$ .

## FERMI ENERGY AND FERMI-DIRAC DISTRIBUTION FUNCTION

### Fermi Energy and generalized Einstein relation

Here, for a presentation simplicity, we change all the sign of various parameters, given in the  $p^+ - X(x)$ - crystalline alloy in order to obtain the same one, as given in the  $n^+ - X(x)$ -crystalline alloy, according to the reduced Fermi energy,  $\xi_{n(p)}(N, r_{d(a)}, x, T) \equiv \frac{E_{Fn(Fp)}(N, r_{d(a)}, x, T)}{k_B T} > 0 (< 0)$ , obtained respectively in the degenerate (non-degenerate) case.

For any  $(N, r_{d(a)}, x, T)$ , the reduced Fermi energy  $\xi_{n(p)}(N, r_{d(a)}, x, T)$  or the Fermi energy  $E_{Fn(Fp)}(N, r_{d(a)}, x, T)$ , obtained in our previous paper (Van Cong and Debiais, 1993), obtained with a precision of the order of  $2.11 \times 10^{-4}$ , is found to be given by:

$$\xi_{n(p)}(u) \equiv \frac{E_{Fn(Fp)}(u)}{k_B T} = \frac{G(u) + Au^B F(u)}{1 + Au^B} \equiv \frac{V(u)}{W(u)}, \quad A = 0.0005372 \text{ and } B = 4.82842262, \quad (11)$$

where  $u$  is the reduced electron density,  $u(N, r_{d(a)}, x, T) \equiv \frac{N^*}{N_{c(v)}(T, x)}$ ,

$$N_{c(v)}(T, x) = 2g_{c(v)} \times \left(\frac{m_{c(v)}(x) \times m_0 \times k_B T}{2\pi\hbar^2}\right)^{\frac{3}{2}} \text{ (cm}^{-3}\text{)}, \quad g_{c(v)} = 1,$$

$$F(u) = au^{\frac{2}{3}} \left(1 + bu^{-\frac{4}{3}} + cu^{-\frac{8}{3}}\right)^{-\frac{2}{3}}, \quad a = [(3\sqrt{\pi}/4)]^{2/3}, \quad b = \frac{1}{8} \left(\frac{\pi}{a}\right)^2, \quad c = \frac{62.3739855}{1920} \left(\frac{\pi}{a}\right)^4, \quad \text{and}$$

$$G(u) \simeq \ln(u) + 2^{-\frac{3}{2}} \times u \times e^{-du}; \quad d = 2^{3/2} \left[\frac{1}{\sqrt{27}} - \frac{8}{16}\right] > 0.$$

So, in the non-degenerate case ( $u \ll 1$ ), one has:  $E_{Fn(Fp)}(u) = k_B T \times G(u) \simeq k_B T \times \ln(u)$  as  $u \rightarrow 0$ , **the limiting condition**, and in the very degenerate case ( $u \gg 1$ ), one gets:

$$E_{Fn(Fp)}(u) = k_B T \times F(u) = k_B T \times au^{\frac{2}{3}} \left(1 + bu^{-\frac{4}{3}} + cu^{-\frac{8}{3}}\right)^{-\frac{2}{3}} \simeq \frac{\hbar^2 \times k_{Fn(Fp)}^2(N^*)}{2 \times m_{c(v)}(x) \times m_0} \text{ as } u \rightarrow \infty,$$

**the limiting condition.** In other words,  $\xi_{n(p)} \equiv \frac{E_{Fn(Fp)}}{k_B T}$  is accurate, and it also verifies the correct limiting conditions. In the following, it will be present in all the electrical-and-thermoelectric coefficients.

In particular, at  $T=0K$ , since  $u^{-1} = 0$ , Eq. (11) is reduced to:  $E_{Fn(Fp)}(N^*) \equiv \frac{\hbar^2 \times k_{Fn(Fp)}^2(N^*)}{2 \times m_{c(v)}(x) \times m_0}$ ,

being proportional to  $(N^*)^{2/3}$ , and also equal to 0, according to the MIT.

In the following, it should be noted that such the accurate expression of  $\xi_{n(p)}(N, r_{d(a)}, x, T)$  is present in all the following electrical-and-thermoelectric.

### FERMI-DIRAC DISTRIBUTION FUNCTION (FDDF)

The Fermi-Dirac distribution function (FDDF) is given by:  $f(E) \equiv (1 + e^{\gamma})^{-1}$ ,  $\gamma \equiv (E - E_{Fn(Fp)})/(k_B T)$ .

So, the average of  $E^p$ , calculated using the FDDF-method, as developed in our previous work (Van Cong, 2018) is found to be given by:

$$\langle E^p \rangle_{FDDF} \equiv G_p(E_{Fn(Fp)}) \times E_{Fn(Fp)}^p \equiv \int_{-\infty}^{\infty} E^p \times \left( -\frac{\partial f}{\partial E} \right) dE, -\frac{\partial f}{\partial E} = \frac{1}{k_B T} \times \frac{e^{\gamma}}{(1+e^{\gamma})^2}.$$

Further, one notes that, at 0 K,  $-\frac{\partial f}{\partial E} = \delta(E - E_{Fn(Fp)})$ ,  $\delta(E - E_{Fn(Fp)})$  being the Dirac delta ( $\delta$ )-function. Therefore,  $G_p(E_{Fn(Fp)}) = 1$ .

Then, at low T, by a variable change  $\gamma \equiv (E - E_{Fn(Fp)})/(k_B T)$ , one has:

$$G_p(E_{Fn(Fp)}) \equiv 1 + E_{Fn(Fp)}^{-p} \times \int_{-\infty}^{\infty} \frac{e^{\gamma}}{(1+e^{\gamma})^2} \times (k_B T \gamma + E_{Fn(Fp)})^p d\gamma = 1 + \sum_{\mu=1,2,\dots}^p C_p^\beta \times (k_B T)^\beta \times E_{Fn(Fp)}^{-\beta} \times I_\beta,$$

where  $C_p^\beta \equiv p(p-1)\dots(p-\beta+1)/\beta!$  and the integral  $I_\beta$  is given by:

$I_\beta = \int_{-\infty}^{\infty} \frac{\gamma^\beta \times e^{\gamma}}{(1+e^{\gamma})^2} d\gamma = \int_{-\infty}^{\infty} \frac{\gamma^\beta}{(e^{\gamma/2} + e^{-\gamma/2})^2} d\gamma$ , vanishing for odd values of  $\beta$ . Then, for even values of  $\beta = 2n$ , with  $n=1, 2, \dots$ , one obtains:

$$I_{2n} = 2 \int_0^{\infty} \frac{\gamma^{2n} \times e^{\gamma}}{(1+e^{\gamma})^2} d\gamma.$$

Now, using an identity  $(1 + e^{\gamma})^{-2} \equiv \sum_{s=1}^{\infty} (-1)^{s+1} s \times e^{\gamma(s-1)}$ , a variable change:  $s\gamma = -t$ , the Gamma function:  $\int_0^{\infty} t^{2n} e^{-t} dt \equiv \Gamma(2n+1) = (2n)!$ , and also the definition of the Riemann's zeta function:  $\zeta(2n) \equiv 2^{2n-1} \pi^{2n} |B_{2n}| / (2n)!$ ,  $B_{2n}$  being the Bernoulli numbers, one finally gets:  $I_{2n} = (2^{2n} - 2) \times \pi^{2n} \times |B_{2n}|$ . So, from Eq. (22), we get in the degenerate case the following ratio:

$$G_p(E_{Fn(Fp)}) \equiv \frac{\langle E^p \rangle_{FDDF}}{E_{Fn(Fp)}^p} = 1 + \sum_{n=1}^p \frac{p(p-1)\dots(p-2n+1)}{(2n)!} \times (2^{2n} - 2) \times |B_{2n}| \times y^{2n} \equiv G_{p \geq 1}(y), \quad (12)$$

$$\text{where } y \equiv \frac{\pi}{\xi_{n(p)}(N^*, T)} = \frac{\pi k_B T}{E_{Fn(Fp)}(N^*, T)}.$$

Then, some usual results of  $G_{p \geq 1}(y)$  are given in **Table 2 in Appendix 1**, being important ones in this work.

## ELECTRICAL-AND-THERMOELECTRIC PROPERTIES

Here, if denoting, for majority electrons (holes), the electrical conductivity by  $\sigma(N, r_{d(a)}, x, T)$ , expressed in  $\text{ohm}^{-1} \times \text{cm}^{-1}$ , the thermal conductivity by  $\kappa(N, r_{d(a)}, x, T)$ , expressed in  $\frac{\text{W}}{\text{cm} \times \text{K}}$ , and Lorenz number L by:

$L = \frac{\pi^2}{3} \times \left(\frac{k_B}{q}\right)^2 = 2.4429637 \left(\frac{\text{W} \times \text{ohm}}{\text{K}^2}\right) = 2.4429637 \times 10^{-8} (\text{V}^2 \times \text{K}^{-2})$ , then the well-known Wiedemann-Frank law states that the ratio,  $\frac{\kappa}{\sigma}$ , is proportional to the temperature T(K), as:

$$\frac{\kappa(N, r_{d(a)}, x, T)}{\sigma(N, r_{d(a)}, x, T)} = L \times T. \quad (13)$$

We now determine the general form of  $\sigma$  in the following.

First, it is expressed in terms of the kinetic energy of the electron (hole),  $E_k \equiv \frac{\hbar^2 \times k^2}{2 \times m_{Cn(Cp)} \times m_0}$ , or the wave number k, as:

$$\sigma(k) \equiv \frac{q^2 \times k}{\pi \times \hbar} \times \frac{k}{k_{sn(sp)}} \times [k \times a_{Bn(Bp)}] \times \left(\frac{E_k}{\eta_{n(p)}}\right)^{1/2},$$

which is thus proportional to  $E_k^2$ .

Then, for  $E \geq 0$ , we obtain:  $\langle E^2 \rangle_{FDDF} \equiv G_2(y = \frac{\pi k_B T}{E_{Fn(Fp)}}) \times E_{Fn(Fp)}^2$ , and  $G_2(y) = \left(1 + \frac{y^2}{3}\right) \equiv G_2(N, r_{d(a)}, x, T)$ , with  $y \equiv \frac{\pi}{\xi_{n(p)}}$ ,  $\xi_{n(p)} = \xi_{n(p)}(N, r_{d(a)}, x, T)$  for a presentation simplicity. Therefore, one obtains:

$$\begin{aligned} \sigma(N, r_{d(a)}, x, T) &\equiv \left[ \frac{q^2}{\pi \times \hbar} \times \frac{k_{Fn(Fp)}(N^*)}{R_{sn(sp)}(N^*)} \times [k_{Fn(Fp)}(N^*) \times a_{Bn(Bp)}(r_{d(a)})] \times \sqrt{A_{n(p)}(N^*)} \right] \times \\ &\left[ G_2(N, r_{d(a)}, x, T) \times \left( \frac{E_{Fn(Fp)}(N, r_{d(a)}, x, T)}{E_{Fn(Fp)}(N^*)} \right)^2 \right] \left( \frac{1}{\text{ohm} \times \text{cm}} \right), \\ \frac{q^2}{\pi \times \hbar} &= 7.7480735 \times 10^{-5} \text{ ohm}^{-1}, A_{n(p)}(N^*) = \frac{E_{Fn(Fp)}(N^*)}{\eta_{n(p)}(N^*)}, \end{aligned} \quad (14)$$

which also determine the resistivity as:  $\rho(N, r_{d(a)}, x, T) \equiv 1/\sigma(N, r_{d(a)}, x, T)$ , noting that  $N^* \equiv N - N_{CDn(NDp)}(r_{d(a)}, x)$ . This  $\sigma(N, r_{d(a)}, x, T)$ -result is an essential one in this paper.

In Eq. (14), one notes that at  $T = 0 \text{ K}$ ,  $\sigma(N, r_{d(a)}, x, T = 0\text{K})$  is proportional to  $E_{Fn(Fp)}^{\frac{3}{2}}$ , or to  $N^*$ . Thus,  $\sigma(N = N_{CDn(NDp)}, r_{d(a)}, x, T = 0\text{K}) = 0$  at  $N^* = 0$ , at which the metal-insulator transition (MIT) occurs.

### Electrical Coefficients

The relaxation time  $\tau$  is related to  $\sigma$  by:

$$\tau(N, r_{d(a)}, x, T) \equiv \sigma(N, r_{d(a)}, x, T) \times \frac{m_{c(v)}(x) \times m_0}{q^2 \times N^*}. \text{ Therefore, the mobility } \mu \text{ is given by:}$$

$$\mu(N, r_{d(a)}, x, T) \equiv \mu(N^*, r_{d(a)}, T) = \frac{q \times \tau(N, r_{d(a)}, x, T)}{m_{c(v)}(x) \times m_0} = \frac{\sigma(N, r_{d(a)}, x, T)}{q \times N^*} \left( \frac{\text{cm}^2}{\text{V} \times \text{s}} \right). \quad (15)$$

Here, at  $T = 0\text{K}$ ,  $\mu(N^*, r_{d(a)}, T)$  is thus proportional to  $(N^*)^{1/3}$ , since  $\sigma(N^*, r_{d(a)}, T = 0\text{K})$  is proportional to  $(N^*)^{4/3}$ . Thus,  $\mu(N^* = 0, r_{d(a)}, T = 0\text{K}) = 0$  at  $N^* = 0$ , at which the metal-insulator transition (MIT) occurs.

Then, since  $\tau$  and  $\sigma$  are both proportional to  $E_{Fn(Fp)}(N^*, T)^2$ , as given above, the Hall factor can thus be determined by:

$$r_H(N, r_{d(a)}, x, T) \equiv \frac{(\tau^2)_{FDDF}}{[(\tau)_{FDDF}]^2} = \frac{G_4(y)}{[G_2(y)]^2}, \quad y \equiv \frac{\pi}{\xi_{n(p)}(N, r_{d(a)}, x, T)} = \frac{\pi k_B T}{E_{Fn(Fp)}(N, r_{d(a)}, x, T)}, \text{ and therefore,}$$

the Hall mobility yields:

$$\mu_H(N, r_{d(a)}, x, T) \equiv \mu(N, r_{d(a)}, x, T) \times r_H(N^*, T) \left( \frac{\text{cm}^2}{\text{V} \times \text{s}} \right), \quad (16)$$

noting that, at  $T=0\text{K}$ , since  $r_H(N, r_{d(a)}, x, T) = 1$ , one then gets at  $N = N_{CDn(NDp)}$ :

$\mu_H(N, r_{d(a)}, x, T) \equiv \mu(N, r_{d(a)}, x, T) = 0$  at  $N^* = 0$ , at which the metal-insulator transition (MIT) occurs.

Finally, the **generalized Einstein relation** is found to be defined (Van Cong, 1980) as:

$$\frac{D(N, r_{d(a)}, x, T)}{\mu(N, r_{d(a)}, x, T)} \equiv \frac{N}{q} \times \frac{dE_{Fn(Fp)}}{dN} \equiv \frac{k_B \times T}{q} \times \left( u \frac{d\xi_{n(p)}(u)}{du} \right),$$

where  $D(N^*, r_{d(a)}, T)$  is the diffusion coefficient,  $\xi_{n(p)}(u)$  is defined in Eq. (11), and the mobility  $\mu(N, r_{d(a)}, x, T)$  is determined in Eq. (15). Then, by differentiating this function  $\xi_{n(p)}(u)$  with respect to  $u$ , one thus obtains  $\frac{d\xi_{n(p)}(u)}{du}$ . Therefore,

$$\frac{D(N^*, r_{d(a)}, T)}{\mu(N^*, r_{d(a)}, T)} = \frac{k_B \times T}{q} \times u \frac{v'(u) \times w(u) - v(u) \times w'(u)}{w^2(u)}, \quad (17)$$

where

$$W'(u) = ABu^{B-1} \quad \text{and}$$

$$V'(u) = u^{-1} + 2^{-\frac{3}{2}} e^{-du} (1 - du) + \frac{2}{3} Au^{B-1} F(u) \left[ \left( 1 + \frac{\frac{3}{2}B}{2} \right) + \frac{4}{3} \times \frac{bu^{-\frac{4}{3}} + cu^{-\frac{8}{3}}}{1 + bu^{-\frac{4}{3}} + cu^{-\frac{8}{3}}} \right]. \quad \text{One remarks}$$

that: (i) as  $u \rightarrow 0$ , one has:  $W^2 \approx 1$  and  $u[V' \times W - V \times W'] \approx 1$ , and therefore:

$$\frac{D_{n(p)}(u)}{\mu} \approx \frac{k_B \times T}{q}, \quad \text{and} \quad \text{(ii) as } u \rightarrow \infty, \quad \text{one has: } W^2 \approx A^2 u^{2B} \quad \text{and}$$

$$u[V' \times W - V \times W'] \approx \frac{2}{3} au^{2/3} A^2 u^{2B}, \quad \text{and therefore, in this **highly degenerate case** and at}$$

$T=0K$ , the **above generalized Einstein relation** is reduced to the **usual Einstein one**:

$$\frac{D(N^*, r_{d(a)}, T=0)}{\mu(N^*, r_{d(a)}, T=0)} \approx \frac{2}{3} E_{Fno(Fpo)}(N^*)/q. \quad \text{In other words, Eq. (17) verifies the correct limiting conditions.}$$

One also notes that, for  $N^* = 0$ ,  $\mu(N^* = 0, r_{d(a)}, T = 0K) = 0$ , as remarked in above, and therefore, for any  $r_{d(a)}$ ,  $D(N^* = 0, r_{d(a)}, T = 0K) = 0$ , according to the MIT.

Further, in the present degenerate case ( $u \gg 1$ ), Eq. (17) gives:

$$\frac{D(N, r_{d(a)}, x, T)}{\mu(N, r_{d(a)}, x, T)} \approx \frac{2}{3} \times \frac{E_{Fno(Fpo)}(u)}{q} \times \left[ 1 + \frac{4}{3} \times \frac{\left( bu^{-\frac{4}{3}} + cu^{-\frac{8}{3}} \right)}{\left( 1 + bu^{-\frac{4}{3}} + cu^{-\frac{8}{3}} \right)} \right], \quad (18)$$

$$\text{where } a = [(3\sqrt{\pi}/4)]^{2/3}, b = \frac{1}{8} \left(\frac{\pi}{a}\right)^2 \text{ and } c = \frac{62.3739855}{1920} \left(\frac{\pi}{a}\right)^4.$$

In **Tables 3n(3p)** given in **Appendix 1**, for given  $x$ ,  $N$  and  $T (= 4.2 \text{ K and } 77 \text{ K})$ , and from Equations (14, 15, 16, 18), the numerical results of the coefficients:  $\sigma$ ,  $\mu$ ,  $\mu_H$ ,  $D$ , expressed respectively in  $(\frac{10^8}{\text{ohm} \times \text{cm}}, \frac{10^8 \times \text{cm}^2}{\text{V} \times \text{s}}, \frac{10^8 \times \text{cm}^2}{\text{V} \times \text{s}}, \frac{10 \times \text{cm}^2}{\text{s}})$ , are found to be decreased with increasing  $r_{d(a)}$ , respectively.

### Thermoelectric Coefficients

First off all, from Eq. (14), obtained for  $\sigma(N, r_{d(a)}, x, T)$ , the well-known Mott definition for the thermoelectric power or for the Seebeck coefficient,  $S$ , is given by:

$$S(N, r_{d(a)}, x, T) \equiv \frac{-\pi^2}{3} \times \frac{k_B}{q > 0} \times k_B T \times \left. \frac{\partial \ln \sigma(E)}{\partial E} \right|_{E=E_{Fn(Fp)}} = \frac{-\pi^2}{3} \times \frac{k_B}{q} \times \frac{\partial \ln \sigma(\xi_{n(p)})}{\partial \xi_{n(p)}}.$$

Then, using Eq. (11), for  $\xi_{n(p)}(N, r_{d(a)}, x, T) \gtrsim 1$ , one gets, by putting

$$F_S(N, r_{d(a)}, x, T) \equiv \left[ 1 - \frac{y^2}{3 \times G_2(y = \frac{\pi}{\xi_{n(p)}})} \right],$$

$$S(N, r_{d(a)}, x, T) \equiv \frac{-\pi^2}{3} \times \frac{k_B}{q} \times \frac{2F_{Sb}(N, T)}{\xi_{n(p)}} = -\sqrt{\frac{3 \times L}{\pi^2}} \times \frac{2 \times \xi_{n(p)}}{\left( 1 + \frac{s \times \xi_{n(p)}^2}{\pi^2} \right)} \left( \frac{V}{K} \right), \quad (19)$$

giving here: (i) at  $\xi_{n(p)} = \sqrt{\frac{\pi^2}{3}} \simeq 1.8138$ , one gets:  $S = -\sqrt{L} \simeq -1.563 \times 10^{-4} \left( \frac{V}{K} \right)$  and at  $\xi_{n(p)} = 1$  one obtains:  $S \simeq -1.322 \times 10^{-4} \left( \frac{V}{K} \right)$ .

Further, the figure of merit, ZT, is found to be given by:

$$ZT(N, r_{d(a)}, x, T) \equiv \frac{S^2 \times \sigma \times T}{\kappa} = \frac{S^2}{L} = (ZT)_{Mott} \times [2 \times F_S]^2, \quad (ZT)_{Mott} = \frac{\pi^2}{3 \times \xi_{n(p)}^2}, \quad (20)$$

giving here: (i) at  $\xi_{n(p)} = \sqrt{\frac{\pi^2}{3}} \simeq 1.8138$ , one gets:  $ZT = (ZT)_{Mott} = 1$ , and at  $\xi_{n(p)} = 1$  one obtains:  $ZT \simeq 0.715$  and  $(ZT)_{Mott} = \frac{\pi^2}{3} \simeq 3.290$ .

Furthermore, from Eq. (19), one gets:

$$\frac{\partial S}{\partial \xi_{n(p)}} = \sqrt{\frac{3 \times L}{\pi^2}} \times \frac{\frac{s \times \xi_{n(p)}^2}{\pi^2} - 1}{\left( 1 + \frac{s \times \xi_{n(p)}^2}{\pi^2} \right)^2}, \quad \frac{dS}{dT} = \frac{\partial S}{\partial \xi_{n(p)}} \times \frac{\partial \xi_{n(p)}}{\partial T}, \quad \text{and} \quad \frac{dS}{dN} = \frac{\partial S}{\partial \xi_{n(p)}} \times \frac{\partial \xi_{n(p)}}{\partial N}, \quad \text{and}$$

$$\frac{d(ZT)}{dT} = \frac{2 \times S}{L} \times \frac{dS}{dT} \quad \text{and} \quad \frac{d(ZT)}{dN} = \frac{2 \times S}{L} \times \frac{dS}{dN}, \quad (21)$$

noting that: (i) at given  $(N, r_{d(a)}, x)$ , and for  $\frac{\partial \xi_{n(p)}}{\partial T} > 0$  (or  $< 0$ ),  $\xi_{n(p)}$  increases (or decreases) for decreasing (or increasing)  $T$ , (ii) at given  $(r_{d(a)}, x, T)$ , and for  $\frac{\partial \xi_{n(p)}}{\partial N} > 0$  (or  $< 0$ ),  $\xi_{n(p)}$  increases (or decreases) for increasing (or decreasing)  $N$ .

Finally, the Van-Cong coefficient, VC, is given by:

$$VC(N, r_{d(a)}, x, T) \equiv N \times \frac{ds}{dN} \left( \frac{V}{K} \right), \quad (22)$$

the Thomson coefficient, Ts, by:

$$Ts(N, r_{d(a)}, x, T) \equiv T \times \frac{ds}{dT} \left( \frac{V}{K} \right), \quad (23)$$

and then, the Peltier coefficient, Pt, as:

$$Pt(N, r_{d(a)}, x, T) \equiv T \times S(V). \quad (24)$$

Now, in the lightly degenerate n(p)-type  $InSb_{1-x}As_x$  alloy, in which  $N = 5 \times 10^{17} \text{ cm}^{-3}$  ( $5 \times 10^{18} \text{ cm}^{-3}$ ), and for  $T=3\text{K}$  and  $80\text{K}$ , the numerical results of various thermoelectric coefficients are reported in Tables 4n(4p) in Appendix 1, noting that their variations with increasing  $r_{d(a)}$  are represented by the arrows: ↗ (increase), and ↘ (decrease), respectively.

Then, in Tables 5n(5p) given Appendix 1 for a given N and with increasing T, and then in Tables 6n(6p) given Appendix 1 for a given T and with decreasing N, the reduced Fermi-energy  $\xi_{n(p)}$  decreases, and other thermoelectric coefficients are in variations, as indicated by the arrows as: (increase: ↗, decrease: ↘).

One notes here that with increasing T (or with decreasing N) one obtains: (i) for  $\xi_{n(p)} \simeq 1.8138$ , while the numerical results of S present a same minimum  $(S)_{\min.} (\simeq -1.563 \times 10^{-4} \frac{V}{K})$ , those of ZT show a same maximum  $(ZT)_{\max.} = 1$ , (ii) for  $\xi_{n(p)} = 1$ , those of S, ZT,  $(ZT)_{Mott}$ , VC, and  $T_s$  present the same results:  $-1.322 \times 10^{-4} \frac{V}{K}$ , 0.715, 3.290,  $-1.105 \times 10^{-4} \frac{V}{K}$ , and  $1.657 \times 10^{-4} \frac{V}{K}$ , respectively, and (iii) for  $\xi_n \simeq 1.8138$ ,  $(ZT)_{Mott} = 1$ . It seems that these results could present a new law in the thermoelectric properties, obtained in the degenerate case.

## CONCLUDING REMARKS

In the  $n^+(p^+) - p(n)$   $InSb_{1-x}As_x$ - crystalline alloy, all the numerical results of electrical-and-thermoelectric coefficients, obtained in our previous work (Van Cong, 2018), were revised and performed, by basing on our following basic expressions.

- (1) The effective extrinsic static dielectric constant law,  $\epsilon(r_{d(a)}, x)$ , due to the impurity size effect, is determined in Eq. (1).
- (2) The generalized Mott criterium in the metal-insulator transition is expressed in Equations (3, 5, 6), showing that  $N_{CDn(CDp)}$  is just the density of electrons (holes) localized in the exponential conduction (valence)-band tail,  $N_{CDn(CDp)}^{EBT}$ , with a precision of the order of  $2.86 \times 10^{-7}$ , as given in our recent work (Van Cong, 2024), and the effective electron

(hole)-density:  $N^* \equiv N - N_{CDn(CDp)} \simeq N - N_{CDn(CDp)}^{EBT}$ , as that observed in the compensated crystals.

**(3)** The ratio of the inverse effective screening length  $k_{sn(sp)}$  to Fermi wave number  $k_{Fn(Fp)}$  at 0 K,  $R_{sn(sp)}(N^*)$ , defined in Eq. (7), is valid at any density  $N^*$ .

**(4)** The Fermi energy for any N and T,  $E_{Fn(Fp)}$ , determined in Eq. (11) with a precision of the order of  $2.11 \times 10^{-4}$  (Van Cong, 1993), and it exists in all the expressions of electrical-and-thermoelectric coefficients.

**(5)** Our expressions for the electrical conductivity,  $\sigma$ , and for the Seebeck coefficient, S, determined respectively in Equations (14, 19) are the basic expressions for determining the electrical-and-thermoelectric coefficients.

**(6)** Finally, in Tables 5n(5p) given Appendix 1 for a given N and with increasing T, and then in Tables 6n(6p) given Appendix 1 for a given T and with decreasing N, the reduced Fermi-energy  $\xi_{n(p)}$  decreases, and other thermoelectric coefficients are in variations, as indicated by the arrows as: (increase: ↗, decrease: ↘). One notes here that with increasing T (or with decreasing N) one obtains: (i) for  $\xi_{n(p)} \simeq 1.8138$ , while the numerical results of S present a same minimum  $(S)_{min} \left( \simeq -1.563 \times 10^{-4} \frac{V}{K} \right)$ , those of ZT show a same maximum  $(ZT)_{max} = 1$ , (ii) for  $\xi_{n(p)} = 1$ , those of S, ZT,  $(ZT)_{Mott}$ , VC, and  $T_s$  present the same results:  $-1.322 \times 10^{-4} \frac{V}{K}$ , 0.715, 3.290,  $-1.105 \times 10^{-4} \frac{V}{K}$ , and  $1.657 \times 10^{-4} \frac{V}{K}$ , respectively, and (iii) for  $\xi_n \simeq 1.8138$ ,  $(ZT)_{Mott} = 1$ . It seems that these results could present a new law in the thermoelectric properties, obtained in the degenerate case.

In summary, all the numerical results of electrical-and-thermoelectric coefficients, given in our previous work (Van Cong, 2018), are now revised and performed.

**Table 5n:** Here, for a given  $N$  and with increasing  $T$ , the reduced Fermi-energy  $\xi_n$  decreases, and other thermoelectric coefficients are in variations, as indicated by the arrows as: (increase:  $\nearrow$ , decrease:  $\searrow$ ). One notes here that with increasing  $T$ : (i) for  $\xi_n \approx 1.8138$ , while the numerical results of  $S$  present a same minimum ( $S_{min.} \approx -1.563 \times 10^{-4} \frac{V}{K}$ ), those of  $ZT$  show a same maximum ( $ZT_{max.} = 1$ ), (ii) for  $\xi_n = 1$ , those of  $S$ ,  $ZT$ ,  $(ZT)_{Mott}$ ,  $VC$ , and  $T_s$  present the same results:  $-1.322 \times 10^{-4} \frac{V}{K}$ , 0.715, 3.290,  $-1.105 \times 10^{-4} \frac{V}{K}$ , and  $1.657 \times 10^{-4} \frac{V}{K}$ , respectively, and (iii) for  $\xi_n \approx 1.8138$ ,  $(ZT)_{Mott} = 1$ .

For  $x=0$ ,

In the degenerate P-  $InSb_{1-x}As_x$  alloy, for  $N = 2 \times N_{CDn}(r_p)$ , one gets:

**Table 6p.** Here, for a given  $T$  and with decreasing  $N$ , the reduced Fermi-energy  $\xi_p$  decreases, and other thermoelectric coefficients are in variations, as indicated by the arrows as: (increase: ↗, decrease: ↘). One notes here that with increasing T: (i) for  $\xi_p \approx 1.8138$ , while the numerical results of S present a same minimum ( $S$ )<sub>min</sub> ( $\approx -1.563 \times 10^{-4} \frac{V}{K}$ ), those of ZT show a same maximum ( $ZT$ )<sub>max</sub> = 1, (ii) for  $\xi_p = 1$ , those of S, ZT, ( $ZT$ )<sub>Mott</sub>, VC, and  $T_s$  present the same results:  $-1.322 \times 10^{-4} \frac{V}{K}$ , 0.715, 3.290,  $-1.105 \times 10^{-4} \frac{V}{K}$ , and  $1.657 \times 10^{-4} \frac{V}{K}$ , respectively, and (iii) for  $\xi_p \approx 1.8138$ , ( $ZT$ )<sub>Mott</sub> = 1.

For x=0,
